

ETHEREUM MAINNET

Fuel Forge Protocol White Paper

Regular FUEL stakes, recurring ETH and wBTC rewards, and FUEL and MORE buy-and-burn pools.

VERSION 1.0 - 5 OCTOBER 2026

This edition describes the proposed Ethereum implementation and the current local contract candidate. It is not a statement that Ethereum contracts have been deployed. Final token, oracle, route, contract addresses and launch time must be confirmed before launch. The public preview contains sample balances and estimates.

thefuelforge.com/ethereum-preview/

01 Overview and release status

A regular Fuel Forge stake locks FUEL principal in a transferable position NFT. The holder may permanently burn additional FUEL for more reward power. Fees from opening positions fund three ETH reward cycles, one 288-day wBTC reward cycle, FUEL and MORE buy-and-burn pools, and a development allocation. There is no PAMP burn allocation and no separate Foundry NFT on Ethereum.

The Solidity candidate has been implemented and locally tested. It has not been deployed to Ethereum Mainnet. The Ethereum website is a design preview, not a live contract interface. Production token, oracle, liquidity route, contract addresses and launch time remain to be confirmed. Any final deployed code and parameters should be checked against this edition before describing it as live.

Component	Ethereum design
Regular position	Lock FUEL for 8-1,000 days; optional permanent FUEL burn; transferable NFT
Reward cycles	8-, 28-, and 88-day ETH pools plus a 288-day wBTC pool for eligible regular positions
Buy and burn	FUEL and MORE only; 10-minute execution intervals
Administrator control	Only each burn pool's daily drip, constrained to 1%-10%

NO PROMISED YIELD

Reward amounts depend on fee inflows, eligible historical power, actual swaps and settlement transactions. Preview estimates are illustrative and are not on-chain entitlements.

02 Position creation and fees

A position locks a positive FUEL principal for a whole-number term from 8 through 1,000 days. The creator can also burn up to three times that principal. Longer terms and the optional burn raise initial reward power. The NFT represents the stake and its unclaimed reward rights; transferring it changes who controls those rights without resetting the term.

The Ethereum entry fee is fixed at 100% of the ETH value quoted for the locked FUEL principal. There is no minimum or maximum fee clamp. The optional extra FUEL burn does not increase the fee. A zero oracle quote or incorrect ETH payment rejects creation. Network gas is additional. The token, oracle and fee receiver are immutable deployment inputs, so the final oracle implementation must be checked before deployment.

INITIAL POWER

$\text{Power} = \text{principal} + \text{floor}(\text{principal} \times (\text{termDays} - 8) / 992) + \text{optional burned FUEL}$. The term bonus is at most one principal and the extra burn is at most three principals, so initial power is at most five times principal.

03 Maturity and withdrawal

There is no early principal withdrawal. At maturity, a seven-day grace period begins during which principal remains fully withdrawable. During the following seven days, principal and power decay linearly to zero. Once the decay period ends, no principal can be recovered. A withdrawal or expiry finalization closes the NFT; earned but unclaimed rewards remain assigned to the current or recorded final owner.

Time	Principal available	Future reward power
Before maturity	Withdrawal unavailable	Positive while otherwise eligible
Maturity through seven days late	Full principal	Full initial power until closure
Seven to fourteen days late	Declines linearly	Declines linearly until closure
Fourteen days late or later	Zero	Zero

04 ETH and Bitcoin rewards

The three ETH reward pools have 8-, 28-, and 88-day cycles. A fourth pool has a 288-day cycle and pays wBTC. Every regular position can participate in the Bitcoin pool: there is no separate Bitcoin mint, Foundry burn, or Foundry NFT. A position must exist before a cycle deadline and have positive historical power at that deadline. A position already withdrawn or fully decayed at the deadline is ineligible for that cycle.

At a cycle close, anyone can process the historical position snapshot in bounded batches. A fixed 0.25% of the gross pool is reserved for the callers processing those batches; 99.75% remains for participants. Each eligible position's share is proportional to its power at the scheduled deadline. Settlement is allowed only after that timestamp; late settlement does not move the deadline.

Rewards are claimed by the current NFT owner, or the recorded final owner if the position has closed. Claims do not expire in the current candidate. Empty cycles and indivisible rounding dust roll forward. The wBTC pool converts ETH funding into wBTC using protected swaps. A conversion is split into chunks of at most 1 ETH, with 10% maximum slippage and fresh quotes; a single conversion call is limited to 32 chunks. A failed conversion rolls back the funding transaction.

05 Immutable fee distribution

Each position fee is routed atomically across the seven destinations below. The percentages, recipients and absence of a PAMP destination are fixed in the Ethereum router candidate. For each payment, non-development allocations round down to whole wei; the development recipient receives the residual wei, nominally 1% plus rounding dust.

Destination	Share of position fee	Purpose
8-day ETH pool	23.68%	Regular position rewards
28-day ETH pool	19.98%	Regular position rewards
88-day ETH pool	15.54%	Regular position rewards
288-day WBTC pool	14.80%	Bitcoin rewards for eligible regular positions
FUEL burn pool	15.00%	Buy and permanently burn FUEL
MORE burn pool	10.00%	Buy and permanently burn MORE
Development	1.00% nominal	Development wallet and rounding remainder

The reward allocations total 74%, burn allocations total 25%, and development receives the remaining 1%. If a required receiver rejects its ETH allocation, the whole entry reverts rather than partially routing its fee.

06 Buy-and-burn execution

The FUEL and MORE burn engines accrue executable ETH on 10-minute intervals. Their daily drip starts at 1% of each pool balance. The one retained administrator control changes the daily drip for each burn pool only within 1%-10%. The burn contracts have no owner fee setter, swap-cap setter, slippage setter, adapter replacement or upgrade path in the current candidate.

Anyone can execute an eligible burn and receives a fixed 1.5% caller reward from the gross ETH used by that execution. The rest is swapped for the target token and sent to the burn address. Each execution uses at most 1 ETH gross, with a fixed 10% slippage ceiling and a fresh quote. If available ETH exceeds the cap, the unspent amount remains queued for later executions. A failed protected swap rolls back the execution.

07 Launch checks and user-facing information

Before launch, verify the final FUEL token, oracle, WBTC route, contract wiring, addresses and start time. The owner's proposed WBTC pool is dexscreener.com/ethereum/0x4585FE77225b41b697C938B018E2Ac67Ac5a20c0; its tokens and liquidity still need validation. Mainnet fork and route-specific tests remain outstanding. Website prices and payouts are estimates. Users pay gas, and settlement, claims and burns need submitted transactions. Publish a new edition with deployed addresses after launch; the Robinhood Chain and PulseChain whitepapers remain separate.
