

WHITE PAPER / VERSION 1.0 / OCTOBER 2, 2026

Burn MORE. Build power.

Permanent token burns. Fixed fee routing. Four recurring payout pools.

Overview

MORE Forge is a burn-only reward protocol deployed on Robinhood Chain and PulseChain. Participants permanently send MORE to the dead address, pay a separate native-coin protocol fee, and select an earning term from 8 to 1,000 days. A position NFT records the burn, reward power and maturity; it does not represent redeemable principal.

Larger burns and longer terms increase power per MORE, up to a combined 5x multiplier. Each eligible position receives a proportional share of funded payout pools at their deadlines. Power ends after the chosen term, while rewards already earned remain claimable.

Core mechanic	Deployed rule
Input MORE	100% sent to the dead address; no principal withdrawal
Protocol fee	100% of burned MORE's main-pair spot value, paid separately in ETH or PLS
Reward power	Amount bonus x term bonus; maximum 5x per MORE
Native-fee routing	84% payout pools / 15% buy-and-burn pools / 1% development
Payout cadences	8, 28 and 88 days in native coin; 288 days in the chain-local Bitcoin token

The participant journey

Buy or hold MORE / Choose a burn and term / Approve and create a position / Earn at eligible deadlines / Claim after settlement

MORE Forge is separate from Fuel Forge. It has no principal-locking option or Foundry eligibility gate. Robinhood and PulseChain operate independently; positions, funds and rewards do not move between them.

This document describes the launch contracts and website as of October 2, 2026. Ethereum and Avalanche are planned, inactive networks. Examples illustrate mechanics and are not forecasts. Contract behavior and chain state determine actual outcomes.

Bigger and longer bonuses

B is MORE in whole-token units; D is an integer term from 8 to 1,000 days. Contract calculations use base units and integer rounding.

Exactly 1,000 MORE burned for 1,000 days reaches 5x. The 1,000-MORE threshold caps the amount bonus, not the burn size; larger burns continue increasing total power at the same maximum multiplier. Power is constant through maturity and zero afterward. The deployed bonus formula has no owner setter.

02 / ECONOMICS

Fixed fee routing.

Allocations below are percentages of the total native-coin protocol fee.

Destination	Fee share	From 100 native units
8-day native payout pool	26.88%	26.88
28-day native payout pool	22.68%	22.68
88-day native payout pool	17.64%	17.64
288-day Bitcoin-token payout pool	16.80%	16.80
FUEL buy-and-burn pool	5.00%	5.00
MORE buy-and-burn pool	5.00%	5.00
PAMP buy-and-burn pool	5.00%	5.00
Development	1.00%	1.00
TOTAL	100.00%	100.00

The fee router distributes each payment atomically. Its destination addresses and allocation percentages are immutable. Each routed allocation is rounded down to native base units; the development recipient receives the remaining nominal 1% plus indivisible rounding dust. The 100-unit column is an arithmetic illustration, not a price or balance estimate.

Fees are funding; power determines shares

The size of a paid fee does not add a separate power bonus. Burn amount and term determine power; routed fees add funding to their respective current cycles and burn pools. Rewards depend on actual pool funding and eligible power at the deadline. There is no fixed APR, guaranteed return or promise to recover the economic cost of entry.

Illustrative entry cost

Assume 1 MORE is worth \$0.01 and the native coin is worth \$2,000. Burning 1,000 MORE destroys \$10 of token value and requires another \$10 in native coin (0.005 native units) as the fee. The combined illustrative cost is \$20 plus gas. These are hypothetical prices, not current market quotes.

Settlement incentives are taken from each funded payout pool: 0.25% goes to callers and the remainder is allocated to participants. Burn execution incentives are taken from that execution's budget: 1.5% goes to the caller and 98.5% purchases tokens for burning. These incentives do not change the fee-routing percentages above.

03 / PAYOUTS AND POSITION RIGHTS

Cycles and reward rights.

The 8-, 28- and 88-day pools pay ETH on Robinhood and PLS on PulseChain. The 288-day pool pays cbBTC on Robinhood and the deployed token labeled wBTC on PulseChain. These are chain-local tokens, not native Bitcoin. Every position eligible at the Bitcoin-pool deadline can participate; no separate Foundry NFT or 288-day minimum term is required.

Fixed UTC deadlines, displayed locally

All cycles use the anchor October 2, 2026 at 17:00 UTC. A cadence of N days closes at anchor + cycle number x N days. The website opened at 21:00 UTC that day, making the first cycles four hours shorter than their full cadence for users entering at opening. Later cycles repeat at fixed UTC; local display changes with time zones and daylight-saving rules.

Cadence	First deadline (UTC)	Eastern local time
8 days	Oct 10, 2026 / 17:00	1:00 PM EDT
28 days	Oct 30, 2026 / 17:00	1:00 PM EDT
88 days	Dec 29, 2026 / 17:00	12:00 PM EST
288 days	Jul 17, 2027 / 17:00	1:00 PM EDT

Eligibility and settlement

A position qualifies when it was created strictly before the deadline and matures at or after it. A position created exactly at a deadline cannot join that closed cycle. A position active exactly through its maturity deadline can qualify. Settlement uses historical power at the deadline even if the transaction happens later.

Anyone can trigger settlement once a funded cycle closes. It is not automatic. The helper processes multiple due pools in one transaction, with a maximum of 60 position-record visits and 20 items per call. The website requests up to 15 records per due pool; larger snapshots need repeated calls. The Bitcoin helper converts pending native funding before settlement, keeping it assigned to the original cycle.

Callers share a total 0.25% settlement incentive, apportioned over processed records. Native pools pay that incentive in native coin; the Bitcoin pool pays it in its reward token. Participant reward = finalized participant pool x eligible position power / total eligible power, rounded down. When no power qualifies, the participant portion rolls into the then-current cycle. Residual claim rounding rolls forward after all eligible positions have claimed.

Claiming and transferring

Rewards become claimable after settlement and have no claim expiry in the deployed vaults. Payment goes to the current position NFT owner, even when another caller triggers the claim. Transferring the NFT transfers all unclaimed and future rewards; it does not restart or extend the term. The website groups up to 20 reward records per claim transaction. Each cycle/position reward can be claimed only once.

04 / BURN POOLS AND WEBSITE

Buy-and-burn mechanics.

Three permissionless buy-and-burn pools

The FUEL, MORE and PAMP pools each receive 5% of every protocol fee on Robinhood and PulseChain. Each pool uses 10-minute intervals and starts with a 1% daily drip setting. Only its owner can choose a drip from 1% to 10%. The rate is used to calculate an execution budget against the pool balance across elapsed intervals; it is not a guaranteed daily purchase or token-price effect.

A caller executes an eligible burn. The gross execution budget is capped, 1.5% is paid to the caller in native coin, and the remaining 98.5% buys the target token. Purchased tokens go to the same dead address used for entry burns. Gas can exceed the caller reward. Delayed calls accumulate budget; execution is still subject to the cap, available funding and swap checks.

Execution setting	Robinhood	PulseChain
Initial daily drip	1%	1%
Allowed owner drip range	1%-10%	1%-10%
Interval	10 minutes	10 minutes
Initial gross execution cap	0.001 ETH	100,000 PLS
Initial maximum slippage	10%	10%
Caller reward	1.5% of gross budget	1.5% of gross budget

The burn-engine owner can also change the execution cap and reduce or restore slippage tolerance within its 10% maximum. These controls affect burn execution, not position fees, power, payout weights or the fixed 5% pool funding. Adapter configuration is a one-time setup. Ownership can be transferred or renounced under the deployed ownership mechanism.

Buying MORE is a separate transaction

The Buy \$MORE tab routes native ETH or PLS through the configured MORE liquidity route and sends MORE directly to the connected wallet. Robinhood uses its V4 route; PulseChain uses PulseX V2. The website adds no platform swap fee, though the underlying pool or hook can charge trading fees. Quotes show a slippage-protected minimum and expire after 60 seconds.

A purchase does not burn MORE, create a position or pay a MORE Forge entry fee. After purchase, the user can fill the burn form with the received amount and review the separate entry. Token approval and position creation are separate wallet confirmations. Users should retain enough native coin for the protocol fee and gas; buying MORE can itself move the fee's underlying spot price.

The website shows daily-drip controls only for the connected owner wallet; owner-only permissions are also enforced by the contract.

05 / SCOPE AND RISKS

What this protocol does - and does not promise.

Pricing and market exposure

The main-pair spot price can move rapidly and can be manipulated, particularly when liquidity is thin. No time average or price-disagreement gate protects the entry fee. Header prices are market display references; the contract's native-coin quote is authoritative for entry. Buying, burning or earning a token does not guarantee its value. Slippage checks can make swaps or Bitcoin conversion revert, delaying execution or settlement.

Irreversibility and operational dependencies

A successful entry permanently sends MORE to the dead address. Rewards depend on funded cycles, eligible power and eventual settlement; recurring pools do not mean perpetual earning power for one position. There is no protocol promise that rewards will exceed the burn, fee or gas cost. Native fees, claim transfers and swaps depend on chain execution and the configured external token, pool, hook and router contracts.

Position NFTs carry valuable reward rights. A transfer changes who can receive already-earned but unclaimed rewards. Bitcoin rewards inherit the deployed token's bridge, custody, liquidity and pricing characteristics; its name or ticker alone does not establish equal value or redemption into native BTC. Wallet security, transaction review and correct chain/token selection remain essential.

Validation and contract authority

Launch preparation included local regression tests, randomized accounting checks, multi-cycle and deadline simulations, chain-fork transaction rehearsals, gas checks, price-swing scenarios, wallet purchase checks and receipt/runtime/configuration verification on both mainnets. These are development checks, not an independent security audit or a guarantee against defects. This whitepaper is technical documentation, not a security certification.

The deployed contracts determine transaction behavior. Website estimates and descriptions can change without changing those contracts. The site's initial opening time was a front-end gate; deployed entry contracts were callable before that interface gate opened. Verify addresses against the public deployment manifest and the chain explorer before interacting.

Future Ethereum and Avalanche scope

Ethereum and Avalanche are listed as future networks and are not active MORE Forge deployments in this release. PAMP is not planned on either chain. The intended MORE Forge routing is 89% to payout pools, 5% each to FUEL and MORE buy-and-burn, and 1% development. Preserving payout weights of 32:27:21:20 gives 28.48%, 24.03%, 18.69% and 17.80% of total fees for the four pools. These are future specifications, not configurable settings of today's Robinhood or PulseChain contracts.

Future chains require separate contracts, token and route selection, testing, deployment and website activation. Adding a chain to the dropdown alone does not connect or launch it. No cross-chain balance or reward portability is implied.

Robinhood Chain deployment.
