

FUEL FORGE / PULSECHAIN

Protocol White Paper

Put your \$FUEL to work.

PLS reward cycles. wBTC Foundry rewards. FUEL, MORE and PAMP buy-and-burn.

VERSION 1.1 - 6 OCTOBER 2026 / LIVE DEPLOYMENT

Live PulseChain deployment. Contract addresses, fees, restricted ownership and cycle deadlines were checked on 6 October 2026. The public PulseChain site transacts with these deployed contracts.

thefuelforge.com/pulsechain/

01 What Fuel Forge does

Fuel Forge uses FUEL in two distinct ways. A Forge position locks principal and may permanently burn extra FUEL for more power. A Foundry NFT permanently burns 100 million FUEL and receives an equal share of its mint cycle's wBTC participant pool. These are separate products; Foundry principal is never returnable.

PulseChain has chain ID 369. PLS is the native currency for fees, gas, Forge rewards and caller rewards. WPLS is used inside swaps. The Foundry reward asset is Ethereum-bridged wBTC, not Robinhood Chain cbBTC. Assets, positions and reward balances do not migrate automatically between chains.

Component	Live rules
Forge position	Positive FUEL principal; 8-1,000 day term; optional burn up to 3x principal
PLS reward vaults	8-, 28- and 88-day global cycles; power-weighted allocation
Foundry NFT	100 million FUEL burned per NFT; 288-day mint-cycle wBTC rewards
Batch mint	1-10 Foundry NFTs per transaction; fee and burn multiplied by quantity
Buy-and-burn	FUEL, MORE and PAMP; ten-minute intervals; user-triggered execution

Architecture and release scope

The deployed suite consists of ForgePosition, three PulsePositionRewardVault contracts, PulseFoundry, PulseFeeRouter, a one-time configured fee forwarder, three ForkBurnEngine contracts, swap adapters and quote contracts, and a SettlementBatcher. The external tokens already exist; Fuel Forge does not issue FUEL, MORE, PAMP or wBTC.

The live website submits wallet-approved transactions to the deployed PulseChain contracts. Mints, withdrawals, burns, settlements and claims require transactions; no automatic keeper is guaranteed.

STATUS

This is a live protocol specification, not an independent audit. Contract timestamps and receipts control outcomes. Market references and payout estimates are informational.

02 Forge principal, burn and power

Create a position by locking a positive amount of FUEL for a whole-number term of 8 through 1,000 days. Optional extra burn can range from zero to three times principal. The locked and burned amounts move in the same transaction. Additional burn is permanent; locked principal is potentially returnable after maturity.

INITIAL POWER

Power = principal + floor(principal x (termDays - 8) / 992) + burned FUEL. The duration bonus ranges from zero to one principal; the burn bonus adds FUEL one-for-one. Initial power cannot exceed five times principal.

100 million FUEL principal	Initial power
8 days / no extra burn	100 million (1x)
1,000 days / no extra burn	200 million (2x)
1,000 days / 100 million extra burn	300 million (3x)
1,000 days / 300 million extra burn	500 million (5x)

Power is an accounting weight attached to the position, not a separate transferable token. More power increases the position's share relative to other eligible power; it does not guarantee a larger currency payout if fee inflows or competing positions change. Extra burn and term do not increase the principal-based mint fee.

Maturity, grace and decay

Maturity is creation time plus the selected number of elapsed 24-hour days. There is no early principal withdrawal. For seven days after maturity, principal and power remain intact. Over the following seven days they decline linearly to zero, with principal and power rounded down separately.

Withdrawing during decay returns only the remaining principal and burns the rest. At fourteen days late, all principal is lost; anyone may finalize an expired position. Closing burns the position NFT but records the final owner for previously earned claims. Later decay does not reduce rewards already allocated at earlier deadlines.

Transferring a live Forge NFT changes control of remaining principal and unclaimed reward rights. It does not reset the term, maturity, burn or power.

03 PLS payout cycles

Three globally scheduled pools collect PLS and allocate it at 8-, 28- and 88-day closes. A position qualifies if created strictly before the deadline, still open at that deadline, and carrying positive historical power then. Any allowed lock term may qualify for any cadence under these rules.

Destination	Share of each Forge fee	Cadence
8-day PLS vault	13.12%	8 days
28-day PLS vault	11.07%	28 days
88-day PLS vault	8.61%	88 days
Foundry wBTC pool	8.20%	288 days

These reward allocations total 41% of a Forge fee. Anyone can settle a closed PLS cycle in bounded batches. Settlement reserves 0.25% of gross PLS for callers; the participant pool is the other 99.75%. Each claim is floor(participant pool x position power at deadline / total eligible power).

An empty eligible set rolls participant funds into the then-current cycle. Claims do not expire in the deployed contracts. Anyone may trigger a claim, but payment goes to the position's current NFT owner or its recorded final owner after closure. Rounding dust rolls forward after all eligible claims.

Closes at 1 PM Eastern

Pulse-specific scheduling keeps payout deadlines at 1 PM America/New_York local time, including daylight-saving changes. Cycle lengths follow the deployed calendar rule; elapsed UTC duration can differ across a DST change.

The live suite was deployed on 30 September 2026. Its payout schedule is anchored to that date and keeps deadlines at 1 PM Eastern using the deployed calendar schedule. First closes: 8 days - October 8, 2026 at 17:00 UTC; 28 days - October 28 at 17:00 UTC; 88 days - December 27 at 18:00 UTC; Foundry - July 15, 2027 at 17:00 UTC. This DST-aware PulseChain schedule differs from the exact 24-hour UTC cadence used by Ethereum and Avalanche.

HYPOTHETICAL PAYOUT

If a PLS cycle contains 10 million PLS gross, callers reserve 25,000 PLS and participants share 9,975,000 PLS. A position holding 5% of eligible power receives 498,750 PLS before rounding. Actual funding and competing power are unknown in advance.

04 Foundry NFTs and wBTC

Each Foundry NFT burns 100 million FUEL and pays a separate PLS mint fee. A ten-NFT batch burns one billion FUEL and pays ten per-NFT fees in one transaction. Quantity multiplies the per-NFT quoted fee; there is no active floor or cap. Gas is additional.

NFTs minted during the same 288-day cycle share that cycle's wBTC participant pool equally. A Foundry NFT participates in its mint cycle only, not automatically in every later cycle. It remains transferable, carrying any unclaimed reward entitlement from that cycle.

Forge entry fee is 100% of the quoted PLS value of principal FUEL. Foundry mint fee is 100% of the quoted value of the fixed 100 million FUEL burn per NFT. Neither fee has an active minimum or maximum. Foundry sends 1% of its fee to development and 99% to wBTC purchases.

At a cycle close, anyone may settle. The caller receives 0.25% of gross wBTC and eligible NFTs split the remaining 99.75%. With no eligible NFTs, participant funds roll forward; residual token-unit dust rolls forward after all claims. Current NFT owners receive unclaimed rewards.

Conversion limits

The fixed conversion cap is 1,000,000,000 PLS per swap after ownership renunciation. A large batch may need multiple swaps. Failed swaps may retry smaller protected chunks within the same transaction, up to 32 completed swaps and 64 attempts. Quote failures, insufficient output or exhausted limits revert the whole mint or conversion; a reverted mint does not burn FUEL or issue NFTs.

Foundry ownership is renounced, so its conversion cap and 10% slippage cannot be changed through former owner setters. Splitting trades does not eliminate price impact. The selected direct WPLS/wBTC route uses PulseX V2; reserves and executable quotes change over time.

HYPOTHETICAL FOUNDRY FEE

If 100 million FUEL is quoted at 25 million PLS, one Foundry NFT costs 25 million PLS plus the permanent 100 million FUEL burn. Of the fee, 250,000 PLS goes to development and 24.75 million PLS buys wBTC. Actual output depends on protected execution.

05 Mint fees and routing

Forge entry fee is 100% of the quoted PLS value of principal FUEL. Foundry mint fee is 100% of the quoted value of the fixed 100 million FUEL burn per NFT. Neither fee has an active minimum or maximum. Foundry sends 1% of its fee to development and 99% to wBTC purchases.

FEE CALCULATION

Forge and Foundry each charge 100% of the quoted FUEL value, without active minimum/maximum fee bounds. Their ownership is renounced. Stored minimum and maximum values are inactive because bounds are disabled.

Forge fee destination	Fixed share
8-day PLS rewards	13.12%
28-day PLS rewards	11.07%
88-day PLS rewards	8.61%
Foundry wBTC purchases	8.20%
FUEL buy-and-burn	33.00%
MORE buy-and-burn	20.00%
PAMP buy-and-burn	5.00%
Development	1.00% nominal, plus rounding dust

Reward shares and the final burn shares are locked. FUEL receives 33%, MORE 20% and PAMP 5% of position fees; the combined burn share remains 58%. The fee router owner is the zero address. Daily drip is separate from fee allocation.

Forge fee routing is atomic: a required receiver failure reverts position creation. Foundry mint fees take their own 1%/99% path and are not redistributed through the Forge fee router. The public site should display confirmed on-chain shares and fee policies rather than treating preview values as live.

06 Buy-and-burn operations

FUEL, MORE and PAMP receive PLS through the fee router. Each has a 1% daily drip at the checked snapshot, spread over 144 ten-minute intervals. Only the 1%-10% daily drip remains adjustable through the restricted controller; caps and slippage cannot be changed by its manager.

Each burn engine has a fixed 1,000,000 PLS gross execution cap and 10% slippage. Unexecuted interval weight accumulates and unspent executable value carries forward. Rate changes checkpoint weight at the old rate. Foundry conversions have a fixed 1,000,000,000 PLS per-swap cap, bounded retries and 10% slippage.

A successful caller receives 1.5% of gross PLS and the other 98.5% buys the relevant token, sent to the dead address. The caller pays gas; small rewards may not cover it. A failed swap pays no caller reward and burns no tokens, although a reverted on-chain transaction still costs gas.

ILLUSTRATIVE TEN-MINUTE INTERVAL

With 1 million PLS in a pool, a 1% daily drip and one newly elapsed interval, gross executable value is about 69.4444 PLS. The caller receives about 1.0417 PLS and about 68.4028 PLS buys tokens. With 144 intervals accrued and an unchanged starting balance, gross is 10,000 PLS before caps and prior executions.

Price references and safeguards

FUEL fee values and swap references come from current executable PulseX V2 router quotes for the selected pools. The fee oracle quotes principal using a pool-based unit FUEL price; it is a valuation for fee calculation, not proceeds guaranteed from selling a large amount. USD figures on the website are informational and do not set on-chain fees.

Burn and Foundry quotes must be valid and no more than fifteen minutes old. Minimum output guards apply the configured shortfall limit. A fresh quote from the same pool is not an independent fair-price oracle and may already reflect a manipulated or thin market. Liquidity changes can cause poor output or reverts even when earlier fork tests passed.

The starting routes are direct WPLS/token pairs on PulseX V2. Do not use the earlier superseded FUEL token/pool or the DAI/wBTC route as the configured direct Foundry route.

07 Owner powers and risks

The daily-rate manager and development wallet is 0x02A0d741FBaebC03A8f0d1A85670bf1CA8C15fA9. Position, Foundry and fee-router ownership is renounced. Burners are owned by the restricted controller 0xc8002615113Beeb9792FBac49D02615456F7Db59. Its only exposed control is each registered burner's daily drip within 1%-10%; it cannot transfer ownership, make arbitrary calls, upgrade, or replace its manager.

Reward-router allocations remain fixed. Swap adapters are configured once. The deployed suite does not expose an owner withdrawal of locked Forge principal or allocated participant rewards. These observations are not an independent security assurance.

Risk	Practical consequence
Contract or integration error	Lost or trapped assets, failed transactions or incorrect accounting; no independent audit.
Thin or manipulated liquidity	Distorted entry fees, material price impact, low permitted outputs or swap failures.
Token and bridge risk	FUEL, MORE, PAMP, PLS and wBTC can lose value. Bridged wBTC adds bridge, custody and underlying-token dependencies.
Irreversible burn / late decay	Optional burn and Foundry burn cannot be recovered. Late Forge principal can decay to zero.
Owner-controlled settings	Only daily drip may change within 1%-10%; other former administrative setters are inaccessible under the final ownership arrangement.
Manual execution	Settlement, claims, burns and withdrawals depend on submitted transactions and gas.
No fixed yield	Payouts depend on actual inflows and eligible shares. Burns do not guarantee appreciation.

Testing status

The September 30 local Solidity run passed 134 tests. Enabling previously gated fork groups produced 39 passing PulseChain checks and 46 passing Robinhood checks, with no remaining failures after correcting an outdated Robinhood fee expectation. PulseChain checks included current routes, burn backlogs, a 20-million-PLS wBTC conversion and ten-NFT stress conversion.

These were local simulations with seeded wallet/token balances where needed; they did not broadcast transactions or establish that users can obtain the tested FUEL quantities. Quotes and liquidity differ across fork snapshots and can change over time. A clean test run does not constitute an audit or a deployment approval.

08 Token and route reference

These are the external token and direct WPLS route references used by the live PulseChain suite. Market prices and liquidity change; verify current executable quotes before a wallet transaction.
