

ROBINHOOD CHAIN MAINNET

Protocol White Paper

Forge positions, recurring ETH and cbBTC rewards, and user-triggered buy-and-burn pools.

VERSION 1.0 - 26 SEPTEMBER 2026

This document describes the deployed Robinhood Chain contracts and readings taken on 26 September 2026. It is a technical explanation, not a guarantee of returns or a substitute for reading the contracts. Owner-controlled settings can change after this date.

thefuelforge.com

01 Executive summary

Fuel Forge is a set of smart contracts on Robinhood Chain that uses FUEL in two different ways. A Forge position locks FUEL as principal and optionally burns additional FUEL to increase its power. A separate Foundry NFT permanently burns 100 million FUEL and participates in a recurring cbBTC reward pool. ETH-denominated Forge mint fees fund three ETH reward pools, the Foundry cbBTC pool, three token buy-and-burn pools, and a development wallet.

The protocol does not promise a fixed yield. Rewards depend on actual fee inflows, the number and power of eligible positions or Foundry NFTs, successful market swaps, and someone submitting the necessary settlement transactions. A position's NFT carries its remaining principal and unclaimed reward rights when transferred. The protocol has not received an independent security audit.

Component	Current mainnet setting	Who acts
Forge position	8-1,000 days; up to 5x initial power	Holder creates; holder withdraws after maturity
ETH reward pools	8-, 28-, and 88-day cycles	Anyone can settle; rewards are claimed
Foundry NFT	100 million FUEL burned per NFT; 288-day cbBTC cycles	Holder mints; anyone can settle
Buy-and-burn	FUEL, MORE, PAMP; 10-minute intervals	Someone presses Execute burn

TWO DISTINCT ECONOMIC POSITIONS

Forge principal is locked and may be returned after maturity. Foundry's 100 million FUEL per NFT is permanently burned at mint. An optional Forge power burn is also permanent.

02 Release scope and architecture

This paper covers the Robinhood Chain deployment with chain ID 4663 and the contract addresses in Section 13. Its launch anchor is 26 September 2026 at 17:00 UTC (1:00 PM Eastern Daylight Time). Deadlines remain fixed in UTC, so their displayed local time may shift when daylight saving time changes. The website at thefuelforge.com is an interface to these contracts; the blockchain records the transactions and controls the outcomes. Any future deployment on another chain would have separate contracts, assets, positions, and cycles.

The principal components are: the ForgePosition ERC-721 contract; three PositionRewardVault contracts for ETH; the ForkFoundry ERC-721 contract and its cbBTC conversion adapter; a one-time fee forwarder and immutable FeeRouter; three ForkBurnEngine contracts with swap adapters; and an optional SettlementBatcher. FUEL, MORE, PAMP, WETH, and cbBTC are existing external tokens, not newly issued Fuel Forge tokens.

The mint and burn transactions require the connected wallet to be on Robinhood Chain. Users pay network gas for their own transactions. Burn execution, pool settlement, and expired-position finalization are intentionally user-triggered; there is no required automated keeper. Delayed execution delays the resulting purchase or claim availability, but does not move a pool's scheduled deadline.

03 Forge positions and power

A Forge position is minted by locking a positive amount of FUEL for a whole-number term from 8 through 1,000 days. The creator may also send up to three times the principal to the burn address. The principal and optional burn are transferred in the same position-creation transaction. The burn cannot be recovered. The initial power is computed once at mint:

INITIAL POWER

Power = principal + floor(principal x (termDays - 8) / 992) + burned FUEL. Because the duration bonus is at most the principal and the burn is at most three times the principal, initial power is at most five times principal.

At the shortest term, the duration component is zero. At 1,000 days, it equals the principal. Burned FUEL adds power one-for-one within the 3x cap. The contract checks the term, positive stake, and burn cap. Power is measured in FUEL-sized units for allocation; it is not a separate token or a balance that can be sold.

The owner may transfer a live Forge NFT. A transfer changes who controls the principal and who may receive unclaimed ETH rewards; it does not reset creation time, maturity, burn, or power. There is no early principal withdrawal. A position may be minted before the first cycle begins, and then becomes eligible for a later scheduled close if it has positive power at that close.

04 Maturity, grace, and decay

Maturity is the mint block timestamp plus the selected number of calendar days. Principal and power remain at their full then-current amounts through a seven-day grace period after maturity. Over the following seven days, both decline linearly to zero. The contract rounds remaining principal and power down separately. After fourteen days past maturity, no principal or power remains.

When the owner acts	Principal outcome	Power at future snapshots
Before maturity	Withdrawal unavailable	Initial power
Maturity through day 7 late	100% of remaining principal returned	Initial power until withdrawn
Day 7 through day 14 late	Linearly decreasing amount returned; rest burned	Linearly decreasing until withdrawn
Day 14 late or later	0 returned; all principal burned	0

Withdrawal closes and burns the position NFT. The contract records the final NFT owner so reward claims already earned before closure still have a recipient. At full expiry, anyone can call `finalizeExpired`, which burns the remaining principal and closes the NFT. Neither maturity nor full expiry automatically sends a transaction; a person must act and pay gas. Previously allocated rewards are not reduced by later principal decay or finalization.

05 ETH reward cycles

Three global ETH pools close every 8, 28, and 88 days from the launch anchor. They are funded with fixed shares of each Forge position fee. A position in any allowed term can qualify for any of these pools if it was created strictly before that pool's scheduled deadline, has positive power at that deadline, and was not closed at or before that deadline. Eligibility is based on the scheduled deadline even when settlement occurs later.

Pool	Share of Forge fee	Share of 41% reward bucket	Cycle
8-day ETH	13.12%	32%	8 days
28-day ETH	11.07%	27%	28 days
88-day ETH	8.61%	21%	88 days
Foundry cbBTC	8.20%	20%	288 days

After an ETH pool closes, anyone may process its historical position snapshot in bounded batches. The pool reserves 0.25% of its gross ETH for the callers who finish those batches. The remaining 99.75% is the participant pool. For an eligible token, the claim is $\text{floor}(\text{participantPool} \times \text{tokenPowerAtDeadline} / \text{totalEligiblePower})$. If total eligible power is zero, the participant amount rolls into the then-current cycle instead of being allocated to nonexistent positions.

Claims are pull-based and do not expire in the current contracts. Anyone may trigger a claim, but ETH is sent to the position's current NFT owner, or its recorded final owner after closure. Thus transferring an NFT transfers its unclaimed reward rights. After all eligible claims, indivisible wei dust rolls into the then-current cycle.

Before settlement, the website's pool balances, power shares, and payouts are estimates. A displayed USD reference is informational and is not an on-chain redemption value. The scheduled snapshot and final on-chain state govern the claim.

06 The 288-day Foundry

Foundry is separate from a Forge stake. Each NFT mints by permanently transferring 100 million FUEL to the burn address and paying an ETH mint fee. There is no per-wallet NFT limit in the contract. Foundry NFTs minted into the same 288-day cycle each receive one equal share of that cycle's cbBTC participant pool after settlement. They do not participate in later Foundry cycles unless newly minted for those cycles.

The Foundry mint fee is currently 0.5% of the live quoted ETH value of 100 million FUEL, bounded between 0.001 and 0.01 ETH per NFT. The owner can change that percentage and those bounds. From a paid fee, 1% goes to the development wallet and 99% is used for ETH-to-cbBTC conversion. The Foundry also receives 8.20% of Forge position fees through the fee router; those ETH inflows are likewise converted to cbBTC. Gas is additional.

At the scheduled cycle close, anyone may settle the Foundry pool. The settler receives 0.25% of gross cbBTC; the remainder is divided equally among eligible NFTs. Claims remain available after settlement. A Foundry NFT can be transferred, and the current owner receives its unclaimed reward. If no NFTs are eligible, or if division leaves smallest-unit dust after all claims, the remaining amount rolls into the then-current Foundry cycle.

CONVERSION CAN FAIL

The Foundry targets a maximum of 0.5 ETH per swap. If a swap fails, the contract can retry smaller protected swaps inside the same wallet transaction, subject to 32 completed swaps and 64 attempts. Quote failures, insufficient output, or exhausted limits revert the entire mint or fee conversion; no FUEL is burned on a reverted mint.

07 Fee policy and routing

Forge's mint fee is currently 0.5% of the quoted ETH value of principal FUEL only; the optional FUEL power burn and selected term do not increase it. The current floor is 0.001 ETH and cap is 0.01 ETH per position. Foundry uses the same current percentage and per-NFT bounds, but its base is the value of the fixed 100 million FUEL burn. The two FeePolicy contracts have separate owner settings.

Destination	Share of each Forge fee	Role
8-day ETH pool	13.12%	Position rewards
28-day ETH pool	11.07%	Position rewards
88-day ETH pool	8.61%	Position rewards
Foundry	8.20%	cbBTC purchases and rewards
FUEL burner	33.00%	Buy FUEL and burn
MORE burner	20.00%	Buy MORE and burn
PAMP burner	5.00%	Buy PAMP and burn
Development	1.00% nominal	Development wallet; also receives indivisible wei dust

The existing FeeRouter's shares and recipients are immutable. The Forge contract sends fees through a one-time configured forwarder to that router. Routing happens atomically: if a required receiver transfer fails, the mint reverts. The Foundry mint-fee path is separate: its 1% development share and 99% cbBTC-conversion share are not passed through this router.

OWNER-CONTROLLED MINT FEES

The owner can set feeBps above zero and up to 10,000 basis points (100%), change the ETH floor and cap, or disable bounds, separately for Forge and Foundry. These capabilities are real powers in the current contracts; the 0.5% and 0.001-0.01 ETH figures describe current settings, not immutable promises.

08 Buy-and-burn execution

The FUEL, MORE, and PAMP burn engines receive ETH from Forge fees. Each currently makes 1% of its pool balance available per day through 144 scheduled 10-minute intervals. The owner may set each engine's daily rate between 1% and 10%. Unexecuted intervals accumulate rather than vanishing. A later execution may cover multiple elapsed intervals, but each transaction is limited by that engine's maximum ETH per execution.

At the 26 September 2026 mainnet reading, all three engines have a 0.001 ETH maximum per execution and a 10% maximum-output slippage tolerance. The owner can change the ETH cap to any positive amount and can lower slippage from its 10% ceiling. An execution pays its caller 1.5% of the gross ETH amount; the other 98.5% is swapped for the relevant token and sent to the dead address. The reward is paid only if the full transaction succeeds. The caller also pays network gas, which can exceed a small reward.

The displayed 'next burn' is an estimate based on current balance, elapsed intervals, and the cap. It is not a promise that every press succeeds. A stale or invalid reference quote, a failed router swap, a price move outside the applicable guard, or insufficient output causes the transaction to revert. The 10% slippage tolerance is a minimum-output check and does not override an earlier quote-integrity check. The burn then waits for a later successful user-triggered execution; there is no automatic keeper.

In simplified terms, newly executable ETH is the current pool balance multiplied by accumulated interval weight divided by $144 \times 10,000$, plus any previously executable amount left by an earlier cap. The result cannot exceed the contract balance. An owner rate change checkpoints the weight already earned at the prior rate; a later execution uses the combined amount and is still capped per transaction.

09 Price references and market execution

Fees and swaps depend on external liquidity pools. Forge and Foundry calculate ETH fees from a live FUEL price oracle. The mint oracle first attempts a checked FUEL quote; on certain volatility or cross-pool disagreement errors it falls back to a live spot quote from the FUEL pool. That fallback helps minting remain available but is less resistant to a temporarily manipulated thin pool. Other quote failures can still prevent a mint.

The FUEL and MORE burn paths compare observations from more than one pool. PAMP does not have a comparable independent reference in the deployed configuration; it relies on its available pool's guarded quote. cbBTC conversion relies on its WETH/cbBTC pool quote and minimum-output protection. These are pool-based safeguards, not a guarantee of an independent fair market price. Small pools can be manipulated, become stale, or lack enough depth at the moment of execution.

For burn and Foundry conversions, the reference quote must be valid and no more than 15 minutes old. The owner-set slippage parameter cannot exceed 10%. A failed swap reverts atomically instead of silently accepting fewer tokens. The protocol cannot promise that every burn, mint, or conversion will complete during adverse market conditions; making that promise would require weakening current protections or changing deployment architecture.

PRICE SOURCE TRADEOFF

The owner accepted thin-pool price references for launch. A cross-pool comparison is useful but does not make two correlated or shallow pools fully independent. FUEL fee spot fallback and PAMP's single-pool reference expose distinct manipulation and availability risks.

10 Governance, ownership, and operations

The current owner and development wallet is 0x02A0d741FBaebC03A8f0d1A85670bf1CA8C15fA9. The owner can change Forge and Foundry fee percentages and bounds; burn-engine drip rates, per-execution ETH caps, and slippage limits; and Foundry conversion cap and slippage within contract constraints. The existing fee router's split and destinations cannot be changed through a setter on that instance. Swap adapters are configured once. Changing an immutable route would require a new deployment and a clear migration plan.

The inspected contracts do not expose an owner function to withdraw locked Forge principal or allocated participant rewards. This is a code-level observation, not a security guarantee. The current system is unaudited. Users should inspect the addresses and current parameters on-chain because owner-controlled values can change without this PDF changing.

Anyone can submit an eligible burn, settle a closed reward cycle, claim a reward, or finalize a fully expired Forge position. Public submission creates no automated schedule: if no one sends a transaction, that action waits. The optional settlement helper can group up to 20 items and at most 60 Forge-position visits in one transaction; larger snapshots use the per-pool batch function. Every submitted transaction requires gas and may revert.

11 Worked examples

Forge power

Suppose a user locks 100 million FUEL for 1,000 days and permanently burns another 300 million FUEL. Base power is 100 million; the duration bonus is 100 million; the burn bonus is 300 million. Initial power is 500 million, or 5x the principal. Only the 100 million locked principal is potentially returnable after maturity.

ETH payout

Suppose one ETH pool closes with 10 ETH gross and all eligible positions total 10 billion power. Settlement reserves 0.025 ETH (0.25%) for callers, leaving 9.975 ETH. A 500 million-power position has a 5% snapshot share and can claim 0.49875 ETH before smallest-unit rounding. This is hypothetical; actual pool funding and total power are unknown in advance.

Foundry mint and reward

If 100 million FUEL is quoted at 1 ETH, the current 0.5% rule yields a 0.005 ETH Foundry mint fee. Of that, 0.00005 ETH goes to development and 0.00495 ETH is used to buy cbBTC, subject to market execution. If a cycle later has 0.1 cbBTC gross and four eligible NFTs, settlement reserves 0.00025 cbBTC for the caller and each NFT can claim 0.0249375 cbBTC, subject to token-unit rounding. Neither quoted value nor funding amount is a forecast.

Burn execution

If an engine has 0.001 ETH executable and that equals its cap, a successful execution pays 0.000015 ETH to the caller and spends 0.000985 ETH on the token purchase. The number of tokens actually burned depends on the realized swap price; an unsuccessful swap pays no caller reward and makes no burn.

12 Material risks and limitations

Risk	Practical effect
Smart-contract and integration errors	Loss, trapped assets, wrong accounting, or failed execution. No independent audit has been performed.
Thin liquidity and price manipulation	Mint fees can reflect a distorted FUEL quote; burns or cbBTC conversion may revert or execute at an unfavorable permitted price.
Asset and counterparty risk	FUEL, MORE, PAMP, cbBTC, ETH, and NFTs may lose value. cbBTC also carries token issuer/custody and bridge or chain risks.
Irreversible burns and delayed withdrawal	Optional Forge burns and Foundry burns cannot be recovered. Forge principal cannot exit early and reaches zero after the late-decay period.
Owner powers	The owner can materially change mint fees and several swap parameters. There is no timelock in the inspected fee-policy code.
Execution dependence	Rewards must be settled and claimed; burns must be triggered. Gas costs, RPC problems, and failed quotes can delay actions.
No fixed yield	Fees and rewards depend on real usage and competing eligible positions. Buy-and-burn does not guarantee token price support.

This document describes mechanisms and risks; it is not investment advice. No APY, token appreciation, or principal recovery after the defined decay period is promised. A wallet confirmation should be reviewed carefully before signing.

How these risks meet in practice

A 10-minute burn slot can be ready while its swap cannot pass the quote guard. The ETH remains in the burner for a later attempt; it is not a guaranteed purchase at the slot boundary. A transaction that reaches the chain and reverts still consumes gas. Likewise, the mint fee's spot fallback can keep minting available during some pool disagreements but may charge a fee based on a briefly distorted price, within the then-current fee bounds. The owner can change those bounds and the percentage.

Settlement callers should compare likely caller compensation with their gas cost. NFT holders should track their own maturity and seven-day grace period; no automation withdraws principal for them. The live app is helpful for monitoring, but the contract timestamps and transaction receipts are decisive.

13 Mainnet contract registry

The addresses below come from the live site's deployment manifest and were checked against public contract getter readings on 26 September 2026. Check the block explorer for current code and state before using an address. Earlier testnet, fork, and superseded mainnet contracts are outside this registry.

Contract	Robinhood Chain address
Forge Position NFT	0x316a858567426Acd376E242b90CeD3742101A58b
Foundry NFT	0x6A6657010862934AC701eDf1E1f246018250953e

14 Verification and versioning

Version 1.0 was prepared from the deployed manifest, the Solidity implementation used for the mainnet candidate and mint-availability replacement, and read-only public-RPC calls to the deployed Forge, Foundry, fee router, reward vaults, and burn engines on 26 September 2026. The public readings confirmed the day and cycle durations, launch timestamp, current fee settings, burn intervals and caps, owner, token references, and router destinations. The figures in Sections 3-11 were cross-checked against the named contract functions.

Because owner-configurable settings and market conditions change, this PDF is a dated snapshot. Future revisions should show a version date, a change log, the exact deployment addresses, and any current parameters that differ from Version 1.0.

Primary references: the deployed contracts at <https://robinhoodchain.blockscout.com/> ; the live interface and manifest at <https://thefuelforge.com/> and <https://thefuelforge.com/mainnet-deployment.json> ; and the Solidity source files ForgePosition.sol, ForgeMath.sol, FeePolicy.sol, PositionRewardVault.sol, ForkFoundry.sol, FeeRouter.sol, ForkBurnEngine.sol, ForkSwapAdapter.sol, and SettlementBatcher.sol in the project source used for this deployment.

Glossary

Term	Meaning in this paper
Principal	FUEL locked in a Forge position and subject to maturity and late decay.
Power	A non-transferable accounting weight attached to the Forge NFT; not a separate token.
Cycle	A globally scheduled period for collecting and allocating one reward pool.
Snapshot	Position power at the scheduled deadline, even if settlement is later.
Settlement	A submitted transaction that closes and allocates a completed cycle.
Gross / participant pool	Gross is the full cycle amount; the participant pool is after the 0.25% caller allocation.
Slippage	Permitted shortfall from a reference output quote; it does not bypass other quote checks.
Burn cap	The owner-set maximum gross ETH spent by one burn execution.

PUBLICATION STATUS

Published protocol documentation dated 26 September 2026. It is not an independent security audit or legal review. Check live on-chain parameters before taking action.
